Quality of care

ABSTRACT

Background: Nursing clinics in rheumatology (NCR) are organizational models in the field of nursing care. There are various NCR models, but there is no consensus on its operational definition. Our objective is to develop quality standards to define and characterize a NCR.

Method: Two-round Delphi method. The panel consisted of 67 experts: rheumatologists and nurses of the nursing working group of the Spanish Society of Rheumatology (SSR). The Delphi questionnaire was developed after a literature and experience review from previous SSR projects. The questionnaire consists of 7 sections: general considerations, standards of structure, process, treatment and monitoring, health education, training and research and quality of care. Each item was scored from 1 (least important) to 9 (most important) or by assigning a number (e.g. waiting days). The degree of agreement among the experts was categorized according to the coefficient of variation (CoV) between very high (CoV ≤ 25%) and very low (CoV > 100%).

Results: The second round questionnaire (182 items) was answered by 46 panelists (34 rheumatologists and 12 nurses). A very important agreement was reached on the general standards of structure, process, treatment and monitoring, health education, training and research and quality of care. Each item was scored from 1 (least important) to 9 (most important) or by assigning a number (e.g. waiting days). The degree of agreement among the experts was categorized according to the coefficient of variation (CoV) between very high (CoV ≤ 25%) and very low (CoV > 100%).

Conclusion: The standards developed in this study would be useful for establishing desirable quality standards of structure and process, and criteria for clinical work, research and teaching that can be used to develop and evaluate the NCRs.

Calidad asistencial

RESUMEN

Introducción: Las consultas de enfermería en reumatología (CER) son modelos organizativos asistenciales en el ámbito de competencias de enfermería. Hay diversos modelos de CER, pero no existe una definición operacional. El objetivo del proyecto es elaborar estándares de calidad para definir y caracterizar una CER.

Método: Estudio Delphi a dos rondas. El panel estuvo constituido por 67 expertos: reumatólogos y enfermeras del grupo de trabajo de enfermería de la Sociedad Española de Reumatología (SER). El cuestionario se elaboró tras revisión bibliográfica y experiencias de proyectos previos de la SER. El cuestionario consta de 7 apartados: consideraciones generales, estándares de estructura, de proceso, de tratamiento y seguimiento, educación sanitaria, formación e investigación y calidad asistencial. Cada ítem se puntuó de 1 (menos importante) a 9 (más importante) o mediante una cifra. El grado de acuerdo de los expertos se categorizó según el coeficiente de variación (CV) entre muy alto (CV ≤ 25%) y muy bajo (CV > 100%).

Resultados: El cuestionario de la segunda ronda (182 ítems) fue respondido por 46 panelistas (34 reumatólogos y 12 enfermeras). Se obtuvo un grado de acuerdo muy importante en los estándares generales, de estructura, de proceso, de tratamiento y seguimiento, educación sanitaria y calidad asistencial. Se encontró menor acuerdo en los estándares relacionados con el tiempo para formación, número de proyectos de investigación propios de enfermería y de publicaciones recomendables.

Conclusión: Los estándares desarrollados en este estudio permitirían establecer mínimos deseables de calidad de estructura, proceso, labor asistencial, investigadora y docente que se pueden utilizar para desarrollar y evaluar CERs.

Introduction

Nursing consultations in rheumatology (NCR) are organizational patient-centered models of care in the field of rheumatology nursing skills. NCRs have been developed in recent years, but their implementation in Spain is still piecemeal. There are various models of NCR but there is no operational definition. Although there is little scientific evidence, one might assume that the NCR optimize each professional skill and contribute to improve the efficiency and quality of care by decreasing costs, especially medical, improving outcomes and quality of life effectiveness and perceived patient outcomes. Given the difficulty to find a definition of NCR in the existing literature and its potential relevance to quality of care, we designed this research project with the overall aim of contributing to the operational definition of an NCR and advance the exploration of those aspects of care, teaching and research of the NCR that could help measure quality.

To address this, Delphi rounds were considered the most appropriate method by experts in the field. The Delphi method was initially developed by the Rand Corporation in the United States to make provisions on military matters after World War III. It has subsequently been used in various areas, both as a predictive tool or as a prioritization strategy formulation. The objective of this technique is to improve judgments and forecasts on issues where there is uncertainty through expert opinion. It is based on the idea that the degree of consensus reached among a group of experts who are familiar with the topics under study gives a very rough idea of the actual size of these items. This technique is very useful to know a problem when it cannot be addressed with experimental approaches. The Delphi technique has been used in a variety of health-related studies. For example, it has been used to make predictions, prioritize design strategies, and especially to develop standards of quality of care and appropriate use of medical technology. This method was designed for this project, which aims to develop quality criteria and standards for defining and characterizing the NCR.

Methods

The project was an initiative of the Nursing Task Force of the Spanish Society of Rheumatology (GTESER), carried out by a scientific committee (CC) consisting of 10 rheumatologists and 3 nurses. In addition, two experienced researchers participated in the methodology design. The project development schedule is shown in Fig. 1.

After defining the objectives of the project, we developed a specific questionnaire addressed to experts in the field, to be applied by Delphi methodology. Basically, the Delphi method is carried out through a series of rounds in each of which questionnaires are distributed with specific questions made to a panel of experts who score their opinions on a quantitative scale. In the second round, and the following if any, experts receive “feedback” on the scores of the rest of the group (in the form of the mean score for each question) and have the opportunity to revise and change their score if they wish. The process ends when it is considered that it has reached a certain level of consensus or that the information obtained is sufficient. This method ensures the anonymity of responses for each respondent (each responder knows what he has responded, how many have responded to what question, but does not know who has answered what). The anonymity of responses prevents the group from being dominated by powerful or vehement individuals, which sometimes are characteristics not necessarily associated to knowledge. In addition, one of the strengths of the Delphi method is that it identifies the degree of agreement, but does not force consensus, but rather weights the views expressed by the number of respondents and the intensity of their responses.

In this project, we used the Delphi method for 2 rounds, with the distribution of questionnaires via email. To prepare the questionnaire for the first round, we constructed a list of features that could describe an NCR or standards that should be met. To do this, we started from the results and experiences of several SER projects: SERAP, ESPERANZA, EMAR from clinical practice guidelines of the SER, and publication of standards of quality of care in rheumatology. The list of features or standards are grouped into the following sections: (1) initial considerations, (2) structural standards, (3) process standards, (4) treatment and monitoring, (5) health education; (6) training/research by the nursing staff of the NCR, and (7) quality of care.

This produced a first draft of the questionnaire sent to members of the CC to verify the relevance of the items, that the statement was not ambiguous and that the way to answer them was appropriate. With the contributions of the CC, the final questionnaire was desig-

Fig. 1. Overview of the development of the project.

The panelists were given 15 days to respond.

After receiving the scores, we performed statistical analysis of the second round of ratings. To categorize the variability in responses and its opposite (the agreement), we used the coefficient of variation (CV) categorized with the following breakpoints: CV less than or equal to 25%=very low variability (high agreement), CV greater than 25% and less than or equal to 50%=low variability (high agreement), CV greater than 50% and less than or equal to 75%=medium variability (medium agreement), CV greater than 75% and less than or equal to 100%=high variability (low agreement), and greater than 100% CV=very high variability (very low agreement).

Due to the circumstances of this study, which only reflects the views of health professionals and patients, it was not submitted for review by the ethics committee.

Results

Of the 67 panelists initially contacted for the first round of the study, responses were received from 49 (73%): 37 rheumatologists (71%) and 12 nurses (92%).

Of these, 46 panelists (34 rheumatologists and 12 nurses) from 12 Spanish autonomous communities responded to the second round (93% of respondents from the first round).

In Tables 1–7 specifies the items distributed in each domain, with their average score, SD, median, minimum, maximum, CV and degree of agreement.

In the items related to general considerations (Table 1) it is worth highlighting the very high degree of agreement in all cases. The panelists believe that an NCR is needed in the Rheumatology department and that it contributes to improving quality of care,
waiting times, resource use, costs, clinical outcomes and patient satisfaction.

Regarding structural standards (Table 2), this showed less agreement on the need for a crash cart (Table 2.1, subcategory of equipment) and the maximum number of people per NCR in a health area and for every nurse (Table 2.3, subcategory of population). There was a very high agreement on standards relating to the training the nurses should have to administer different questionnaires, especially the visual analog scale (VAS) and the Health Assessment Questionnaire (HAQ) and metrology training in rheumatoid arthritis regarding the Disease Activity Score 28 (DAS28) and the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and the Bath Ankylosing Spondylitis Functional Index (BASFI).

In the items related to process standards we found a very high degree of agreement in all those included in the subcategories of Tables 3.1–3.3, except for the minimum number of days per week that the NCR should be available (Table 3.2) and the need for an appointment reminder to the patient the previous day (Table 3.3). As can be seen in Table 3.5, regarding the time of visit standards, we found a much lesser degree of agreement according to numerous items, highlighting a very low agreement in the minimum estimated time before scheduling appointments.

The items related to standards of care and follow-up (Table 4) and health education (Table 5) had a very high degree of agreement except an agreement only measured as high in “nursing training in relaxation techniques for application to patients” (Table 5). The items in Table 6, relating to training and research standards, had a greater variability, being medium, low or very low in those regarding days required for continuing education and auxiliary nursing, number of research projects by nursing and number of national publications, respectively. For all other items there was a very high degree of agreement.

The items related to care quality standards (Table 7) had a very high agreement, except the maximum time to resolve claims, the

maximum time for clinical queries and months the clinics should distribute questionnaires of perceived quality.

Discussion

To our knowledge, this is the first published study intended to clarify the features an NCR should have.

An important finding in this study was the high degree of agreement (CV<25%) achieved in most of the standards. Those related to initial considerations stand out as most important aspects considered, stating that the NCR is an essential component of Rheumatology departments and helps to improve the quality of care.

The structure standard underscores the need for the NCR to be located within the Rheumatology department. The most important minimum requirements are to have its own phone line, patient education materials, sphingomanometer, and scales to weigh and measure patients. In addition, the NCR nursing staff should be trained primarily for the performance of the VAS, HAQ, DAS28, BASDAI and BASFI.

Within the structure standards, there was also good agreement in establishing the average maximum population (about 200 000 inhabitants) to justify establishing an NCR in a health area and the maximum number of rheumatologists who share an NCR nurse (3, 9). In contrast, the agreement was lower in deciding the average maximum population per nurse in an NCR (about 165 000 inhabitants).

In the standard process it is worth noting the high degree of agreement that exists in almost all of the items. In the section on the NCR nursing staff, the panelists considered essential that the nursing staff managed their own agenda, kept a patient registry, applied protocols for the management of patients with rheumatologic disease and coordinated communication with the rheumatologist, physical therapist, occupational therapist, psychologist and social worker. Furthermore, the availability of NCR appointments must be at least 3 days/week.

In point of care activities of NCR, health education to patients and families, telephone assistance, global health assessment by the patient (VAS), pain VAS assessment and recording different nursing activities are considered essential. In patients with rheumatoid arthritis, functional capacity assessment by the HAQ is considered necessary. For patients with ankylosing spondylitis, the most important is the assessment of disease activity through the BASDAI and functional capacity assessment using the BASFI. For patients with osteoarthritis, the most important care activities of nursing personnel in the NCR should be to provide information on physical measures (hot-cold) and provide information to patients on an individual basis. For patients with chronic low back pain, indi-

Among the research areas in which the NCR could participate we found (scale of 1–9)

- Diagnostic and prognostic factors
- Efficacy studies (clinical trials) of treatments
- Efficacy studies (in practice) of treatments
- Safety Observatories
- Observatories adherence
- Genetic testing: biological sampling and clinical information
- Obtaining blood samples for clinical trials
- Economic NCR assessment studies

The following should be included among the NCR nursing staff training topics (scale of 1–9)

- Advances in pharmacological and non-pharmacological treatments
- Update on diagnosis
- Update on measurement tools (DAS28, CDAl, HAQ)
- Healthcare Management
- Research Methodology
- Stress Management for monitoring the patient
- Coaching through motivational talks, seminars, workshops
- Communication skills to promote kindness, understanding, empathy, sympathy, and creating a climate of trust
- The NCR should be able to train nursing students and other professionals

Issues to consider in the satisfaction survey of patients seen in the NCR

- Care, kindness
- Information provided by the nursing staff
- Frequency of visits
- Visits duration
- Waiting time to first NCR visit
- Waiting time to be seen once in the NCR office
- Doubt resolution
- Accessibility
- Telephone contact availability
- Physical space in which the query takes place
- Privacy consultation of the nursing Coordination with physician

Standard (continuous variable)

- Maximum time to resolve the claims of a patient in the NCR (days)
- Maximum time to answer any questions a patient has in by the NCR clinic (h)
- Number of months the health quality questionnaires are received by patients of the NCR

visualized information and individualized advice on exercise and posture are the most prominent. For patients with osteoporosis this also applies, as individualized information and recommendations on adequacy of housing to prevent falls are the most necessary. For patients with lupus, individualized information stood out. In all conditions individualized information by the nurse stands over group information.

Panels considered as important those aspects related to the registry of the NCR nursing staff. The most important item was to note either in the medical record (patient history) or in a database, patient assessment, medication sheet, activity planning, implementation of the activity and its assessment. It is of utmost importance to ensure patient confidentiality of the data. Furthermore, the patient history should always note the date and time in a clear and concise manner. The nurse’s signature must appear on all medical records. All this information should also complete NCR treatment protocols.

There was also a high degree of agreement for some of the time standards, but not for the whole. Of note was the ‘very low’ degree of agreement when asked how far in advance the patient should be able to make an NCR appointment. At this point, the panelists issued responses ranging between 0.3 and 70 months. The lack of agreement on this point may be due to different mechanisms established in each department to meet the urgent demands or preference of patients, and the unscheduled tasks and availability for first appointment of different professionals (e.g. residents, physicians, nursing staff, secretary). It is desirable that these responsibilities are well defined to avoid delays or redundancies in unscheduled care.

By studying the results of treatment and monitoring standards, the majority of opinions highlighted the need for a protocol for monitoring disease modulating biological and nonbiological drugs, and applying it. It is also very important to ask the patient for their adherence to treatment at each visit.

Among the NCR health education standards, the panelists believe that it is essential to teach patients treated with subcutaneous drugs to administer them properly and train when in self-medication.

In the block of training and research standards of the NCR staff, there is little agreement among the panelists on how to quantify the value of the indicators. The agreement is very low at the time of deciding the number of days per year of training for nursing assistants, standard on which the panelists ranged from a day to 90 days (mean: 8 days). In the case of nursing training days, and showing better agreement, it scored, on average, 11 days a year. This variability may be explained by the different professionals that made up the group of experts who participated in the study, rheumatologists and nurses belonging to GTESER.

There was more consensus in deciding the research and staff training issues of the NCR. The most valuable lines of research were searched all those available in previous publications, including those of SER itself. With the identified standards, we developed a preliminary list of those that should have an NCR. This list was corrected and extended by SER researchers who had participated in other projects such as the SERAP and ESPERANZA programs. It is therefore unlikely that this list missed any relevant standards, although it is possible that new standards may be defined with increased attention on NCR and their numbers.

Another possible limitation in the development of standards may be due to the influence of the opinions of some experts over others. In this project, influence among panelists was avoided using the Delphi method, since interactions occur in the second round to maintain the anonymity of responses. This method has proved its worth in the development of standards similar to those in this study.14,26–30

In any case, the standards developed in our study are quite consistent with recent recommendations made recently by the European League Against Rheumatism (EULAR) on the role of nurses in the management of chronic inflammatory arthritis.31

In conclusion, the definition of these standards may allow us to establish minimum desirable qualities in different dimensions, such as structure, process and outcome, both in clinical work and in research and teaching. The usefulness of these standards can be multiple, not only for health professionals but also in relationships with patients and patient organizations, institutions and health services and administration.

Ethical Responsibilities

Protection of People and Animals. The authors state that no experiments were performed on humans or animals.

Data Confidentiality. The authors state that no patient data appear in this article.

Right to Privacy and Informed Consent. The authors state that no patient data appear in this article.

Funding

Project undertaken by the Spanish Foundation of Rheumatology and sponsored by Abbott.

Conflict of Interest

Dr. D. Santiago Muñoz states the following conflicts of interest: advisorships with Roche, Celgene, and Pfizer. President of the Spanish Society of Rheumatology. Current Participation in clinical
trials or studies sponsored by UCB, Roche, Abbott, MSD, Bioiberica, Celgene, Pfizer and the Spanish Foundation of Rheumatology. The other authors declare no conflicts of interest.

Acknowledgments

We thank the panel of experts who responded to the Delphi questionnaires for their time and dedication in preparing their responses, without which this study would not have been possible.
