To the Editor,

Endocrine disorders often have rheumatic manifestations, which can sometimes be the first characteristic of the disease. Among these disorders is hyperparathyroidism, which is classically manifested by the presence of kidney stones, fractures, pancreatitis and psychiatric disorders.1 A woman aged 57 was admitted due to widespread pain, sleep disturbances, headache, fatigue and loss of function of upper and lower limbs. Nine months earlier she had been diagnosed with fibromyalgia, having been treated with fluoxetine 20 mg/day and clonazepam 1 mg/day without improvement. Laboratories prior to admission showed an erythrocyte sedimentation rate (ERS) 31 mm/h, hematocrit 35%, hemoglobin 11 mg/dl, CPK 62 U/l (VN to 165), C reactive protein (–). At the time of admission, the physical examination of the patient showed no peripheral arthritis, muscle strength was normal in the neck and pelvic girdle, and she presented positive trigger points for fibromyalgia (18/18). Analysis showed ESR 49 mm/h, serum calcium 13.5 mg/l (VN 8.5–10.5), phosphate 1.9 mg/l (VN 2.4–4.1), alkaline phosphatase 900 U/l (230–460 V). Radiographs showed radiolucent lesions in the clavicle and salt and pepper lesions of the skull. The abdominal ultrasound showed a 6 mm kidney stone at the middle calyx of right kidney. The chest CT observed lytic sack lesions, and a neck ultrasound showed a 6 mm kidney stone at the middle calyx of right kidney. The chest CT observed lytic sack lesions, and a neck ultrasound showed a 6 mm kidney stone at the middle calyx of right kidney.

The levels of parathyroid hormone (PTH) were found, receiving treatment for hyperparathyroidism, muscle strength was normal in the neck and pelvic girdle, mimicking polymyalgia rheumatica, is frequent, and arthritis can also mimic gout or pseudogout. Our patient reported sleep disturbances, fatigue, strength loss of arms and legs and generalized musculoskeletal pain; symptoms did not improve with drug therapy. Other clinical manifestations are at the neuromuscular level, paresthesias and cramps. The improvement of symptoms after excision of the adenoma suggests the causal relationship with hyperparathyroidism. Thomas and Podduturu reported a patient with a previous diagnosis of fibromyalgia who received multiple treatments with no improvement, in whom high levels of PTH were found, receiving treatment for hyperparathyroidism, which led to the resolution of pain.8 In conclusion, we believe that routine determination of serum calcium and phosphorus should be performed in patients with generalized pain syndromes in which fibromyalgia or polymyalgia rheumatica is suspected.

Hyperparathyroidism, A Forgotten Cause of Musculoskeletal Pain

Hiperparatiroidismo, una causa olvidada de dolor músculo-esquelético difuso
