Adalimumab

ABSTRACT

A 34-year-old man with an 8-year history of outbreaks of oral and genital ulcers presented with high fever and skin lesions that had developed 21 days earlier, without abdominal pain. Computed tomography revealed intestinal perforation requiring surgery. After treatment with corticosteroids and azathioprine proved to be ineffective, it was switched to adalimumab.

Enfermedad de Behçet con perforación intestinal: a propósito de un caso

RESUMEN

Paciente de sexo masculino de 34 años con antecedente de úlceras orales y genitales que cursaban en brotes de 8 años de evolución, se presenta con fiebre elevada y lesiones en piel durante 21 días, sin dolor abdominal. Se realiza tomografía computarizada, observándose perforación intestinal, por lo que es intervenido quirúrgicamente. Es tratado con corticoides y azatioprina. Luego, por falta de respuesta, se le administra adalimumab.

Introduction

Behçet's disease (BD) is a chronic multisystemic inflammatory disease characterized by outbreaks of vascular involvement in some lesions, but not in others that affect brain parenchyma or in pseudoacne. Thus, whether it should be considered a vasculitis is a matter of debate.

Case Report

The patient was a 34-year-old Caucasian who had been hospitalized with a syndrome that had begun 21 days earlier. It consisted of high fever of unknown origin, together with weakness and a

nodular eruption that left scars in both upper and lower limbs, and no ophthalmologic manifestations.

He reported an 8-year history of intermittent painless oral and genital ulcers that appeared and disappeared spontaneously, with no definite diagnosis.

Laboratory tests showed: erythrocyte sedimentation rate >120 mm/h, C-reactive protein 400 mg/dL and negative results on immunological tests (antiphospholipid antibodies, antineutrophil cytoplasmic antibodies, anticardiolipin antibodies and the venereal disease research laboratory test). Antigen tests, viral serology and a test for human leukocyte antigen (HLA)-B27 were negative. An electrophoretic protein profile was normal. Immunoglobulin (Ig) A level was 443 mg/dL. Parasitological analysis of stool was negative.

Thoracic and abdominal computed tomography revealed bilateral pleural effusion, pneumoperitoneum, peritoneal membrane thickening, free fluid in the peritoneal cavity and enlarged lymph nodes. Therefore, he was scheduled for surgery, and was found to have numerous intestinal perforations (Fig. 1). It was necessary to perform subtotal colectomy and ileostomy. Treatment with meprednisone at 40 mg/day resulted in a favorable clinical course. The dose was reduced to 8 mg/day, accompanied by azathioprine

at 100 mg/day, which resulted in 1 year without relapses. A video recording of a follow-up colonoscopy showed active lesions, and he began to receive 40 mg of subcutaneous adalimumab every 15 days,^{1–3} which achieved clinical and histopathological remission after 4 months of treatment.⁴

Ancillary histopathological studies of a tissue specimen demonstrated colonic ulceration with perilesional inflammation; a skin biopsy revealed septal lobular panniculitis with mononuclear and polymorphonuclear cell infiltrate; and nonspecific inflammation was observed in the scrotal ulcer. Testing was positive for HLA-B52⁵ and negative for HLA-B51. The pathergy test was negative.

Conclusions

Patients with Behçet's disease can experience oral and genital ulcers for years, with no definitive diagnosis, and consult their physicians only when serious complications arise. Since the diagnosis is mainly clinical, primary care physicians should be familiar with the characteristics of this disease,⁶ especially in countries like Argentina in which the prevalence is low and the evidence is concealed in a variety of symptoms that must be associated to discover it. Therefore any delay in the diagnosis increases the rates of mortality and morbidity affecting patients with BD.

To date, when gastrointestinal involvement is detected, good responses have been achieved with sulfasalazine, azathioprine and corticosteroids at low or high doses or as pulse therapy, as well as with pulse cyclophosphamide. However, in the case of intestinal perforation, the treatment must be aggressive and can be initiated directly with adalimumab.⁷
