Hydrogen sulphide; Allergic rhinitis; Cystathionine \(\beta\)-synthase; Cystathionine \(\gamma\)-lyase; Guinea pig; Real time RT-PCR; Nasal mucosa

Abstract

Background: The present study was designed to explore the possible changes in endogenous hydrogen sulphide (H\(_2\)S), a novel gasotransmitter, on the pathogenesis of allergic rhinitis (AR).

Methods: AR guinea pig model was established by nasal ovalbumin sensitisation. Guinea pigs were divided into four groups: Saline control, AR sensitised, sodium hydrosulphide (NaHS) treated, and propargylglycine (PPG) treated group. The frequency of sneezing and nose rubbing was recorded. Leukocyte infiltration in nasal lavage fluid (NLF) and plasma H\(_2\)S level were measured. Expression of Cystathionine-\(\beta\)-synthase (CBS) and Cystathionine-\(\gamma\)-lyase (CSE) mRNA as H\(_2\)S-producing enzymes in nasal mucosa was determined by real time Reverse Transcriptase-Polymerase Chain Reaction (RT-PCR).

Results: The frequency of sneezing and nose rubbing, and levels of leukocyte infiltration in NLF were higher than those of control (\(P<0.01\)), but plasma H\(_2\)S in sensitised guinea pigs was lower than those of control (\(P<0.05\)). From the results of RT-PCR, it was found that the expression of CSE was higher than CBS in nasal mucosa, and in sensitised guinea pigs it was lower than that of control (\(P<0.05\)). NaHS successfully increased the level of H\(_2\)S and alleviated the symptoms of AR accompanied by up-regulation of CSE as compared with AR group (\(P<0.05\)). PPG significantly suppressed the expression of CSE and decreased the H\(_2\)S level, yet also aggravated the symptoms of AR.

Conclusion: H\(_2\)S level may be negatively correlated with the process of inflammation and positively correlated with expression of CSE in nasal mucosa. The endogenous H\(_2\)S pathway is down-regulated in AR.

Introduction

Rhinitis, especially allergic rhinitis (AR), continues to be a major health problem and although some treatments are available, none is ideal. Research on the role of the gas signal messenger such as nitric oxide (NO) and carbon monoxide (CO) in allergy medicine is a rapidly emerging field. However, the molecular mechanisms of AR are still poorly understood, and researchers are seeking novel endogenously produced gasotransmitters to investigate their possible roles in the pathogenesis of allergic inflammation. Recently, hydrogen sulphide (H\(_2\)S) was found to be the third endogenous signalling gasotransmitter because of its endogenous metabolism and physiologic functions. Now H\(_2\)S is increasingly recognised as a member of a growing family of “gasotransmitters”, together with its two counterparts, NO and CO.

H\(_2\)S was only recognised as a kind of toxic gas in contaminated environments with a strong odour of rotten eggs for a long time, and its major effects were intoxication of the central nervous system and inhibition of respiratory system. Endogenous H\(_2\)S may be generated by two pyridoxal-5'-phosphate-dependent enzymes: cystathionine \(\beta\)-synthase (CBS) and cystathionine \(\gamma\)-lyase (CSE) in mammalian tissues, which use L-cysteine as the main substrate. The expressions of these two enzymes are tissue-type specific. H\(_2\)S is directly produced in myocardial tissues, arterial and venous tissues by CBS, and in some tissues such as the nervous system, CBS is only needed for the generation of H\(_2\)S. Otherwise, the expressions of CBS and CSE are both identified in several mammalian tissues, including liver, kidney, brain, ileum, and blood lymphocytes.

Recent data suggest that H\(_2\)S may contribute to many inflammatory processes such as asthma, acute pancreatitis, endotoxaemia, and COPD. This demonstrated that H\(_2\)S plays a key role in modulating leukocyte adhesion to vascular endothelium, leukocyte infiltration, and oedema formation, which are characters of inflammation. To clarify the role of endogenous H\(_2\)S in the pathogenesis of AR, we investigated the level of plasma H\(_2\)S in guinea pigs with AR. Clinical symptoms of animals such as sneezing and nose rubbing, and leukocyte infiltration in nasal lavage fluid (NLF) were studied as non-invasive markers of inflammation. The expressions of CBS and CSE of nasal mucosa were also investigated by real time RT-PCR. Sodium hydrosulphide (NaHS) and propargylglycine (PPG) were used as donor and inhibitor of H\(_2\)S respectively in our study, and PPG is a specific inhibitor of CSE, which can suppress H\(_2\)S production in tissues. Through regulated H\(_2\)S level by NaHS and PPG, we investigated the changes of H\(_2\)S on the inflammation process of AR.

Materials and methods

Material and animal model

Twenty-four aged healthy male Hartley guinea pigs, weight 230–280g (National rodent laboratory animal resources, Shanghai branch, China) were taken and divided into four groups: Saline control group, AR sensitised group, NaHS treated group, and PPG treated group. The animal models of allergic rhinitis were prepared according to the methods made by Al Suleimani M et al. Guinea pigs (n = 18) were initially exposed to 1% ovalbumin (10mg/kg, Sigma Inc.MD ) in saline given as a 1% aerosol twice for 10 min each, 7 days apart. On days 14, 15 and 16, a booster of 1% ovalbumin in saline was instilled intranasally at a volume of 20\(\mu\)l/nostril/day into both nostrils. On day 21 guinea pigs were challenged with 2% ovalbumin in saline instilled intranasally at a volume of 20\(\mu\)l/nostril in each nostril. Eighteen sensitised guinea pigs were divided into three groups, one was continually treated with OVA as AR group. In the second group, named as NaHS group, animals (n = 6) were intraperitoneally administered NaHS (Sigma Inc. MD) at a dose of 14\(\mu\)mol/kg/day, 12 h after every nose inspiration with ovalbumin and continually for two weeks. In the third group, named as PPG group, animals (n = 6) were intraperitoneally administered PPG (Sigma Inc.MD) at a dose of 30 mg/kg/day immediately after every nose inspiration with ovalbumin continually for two weeks too. Control animals (n = 6) were challenged in a similar manner by using saline.

Observation of sneezing and nose rubbing and assessment of leukocyte infiltration

Frequency of sneezing and nose rubbing were assessed as previously described by Al Suleimani M et al. with modifications. They were counted directly following nasal challenge, and for 30 min thereafter. A sneeze was characterized by an explosive inspiration just after deep inspiration and an external perinasal scratch with the animal’s forelimbs characterized a nose rub. NLF was collected from guinea pigs 1 h post-challenge as follows: nasal cavities were washed with 2\(\mu\)l of pre-warmed saline infused from the tracheal side. NLF was collected from the anterior naris and total cell count was assessed using a standard haemocytometer. Leukocytes were counted under light microscope at power 40\(\times\), and the following formula was used:

\[
\text{Number of cells/ml} = \frac{\text{total number of cells counted} \times \text{dilution factor}}{1000 \times \text{total volume counted}} \times 1000
\]

Measurement of plasma H\(_2\)S concentration

Guinea pigs were anaesthetised by intraperitoneal administration of pentobarbital (40 mg/Kg). 1ml blood was collected from heart through direct cardiac puncturation, avoiding air contact. A sample of plasma (0.1 ml) was added to a test tube containing 0.5 ml of 1% zinc acetate and 2.5 ml of distilled water, then 0.5 ml of 20 mmol/L N,N,N-dimethyl-p-phenylenediamine dihydrochloride in 7.2 mol/L HCl and 0.4 ml of 30 mmol/L FeCl\(_3\) in 1.2 mol/L HCl were also added to the same test tube for 20 min of incubation at room temperature. The protein in the plasma was removed by adding 1 ml of 10% trichloroacetic acid to the solution and centrifuging it. The optical absorbance of the resulting solution at 670nm was measured with a spectrometer (Lamba Bio, Perkin Elmer Inc, MD). H\(_2\)S concentration in the solution was calculated against the calibration curve of the standard NaHS solution.
Total RNA extraction and cDNA synthesis

The guinea pigs were sacrificed by rapid decapitation. Biopsies of nasal mucosa were taken from the inferior turbinate and put in liquid nitrogen immediately. They were then minced with a scalpel on dry ice and transferred immediately to 2 ml polypropylene tubes, homogenised and total RNA was extracted using Trizol™ reagent (Invitrogen Inc, MD) following the manufacturer’s instructions. The concentration and purity of RNA were determined spectrophotometrically. Then the synthesis of cDNA was performed according to a cDNA synthesis kit (PrimeScript RTase, TaKaRa Inc, Japan).

Real time reverse transcriptase-polymerase chain reaction for CBS and CSE mRNA expressions

To determine the expressions of the CBS and CSE gene in nasal mucosa, fluorescent quantitative real time RT-PCR assay was performed. The sequences of the primers (TaKaRa Inc, Japan) specific for CBS and CSE were performed with sense (CBS: CCAGGACTTGGAGGTACAGC, CSE: TCCGGATGGAGAAACACTTC) and antisense (CBS: TCGGCACTGTGGTAATGT, CSE:GCTGCCCTTTAAGCTTGACC) primers, with an expected size of the amplified sequence of 155 bp for CBS and 400 bp for CSE. β-actin was used as control (sense: ACCCTTAAGGCAAACGTGAAG, antisense: TCATGAGGT

![Figure 1](http://www.elsevier.es) The typical amplification and melting curves of real-time RT-PCR for CSE(A), CBS(B) and β-actin(C). The figure shows a sharp peak with a melting temperature of CSE(Tm A) of 84 °C, CBS(Tm B) of 86 °C and β-actin (Tm C) of 90 °C.
AGTCTGTC AGGT, 240 bp). Then the incubation of cDNA and primer was performed at 95 °C for 5 min and the PCR reaction proceeded for 45 cycles: 95 °C for 20 s, 57 °C for 20 s, and 72 °C for 20 s in a programmable thermal cycler (Line-Gene real-time PCR detection system, bioer Inc, China) using a thermostable Taq DNA polymerase (SYBR PrimeScript Ex Taq, TaKaRa Inc, Japan) final incubation at 72 °C for 7 min. Fluorescent product was measured by a single acquisition mode at 86 °C after each cycle. After the completion of PCR amplification, a melting curve analysis was performed. Fig. 1 shows a sharp peak with a melting temperature (Tm) of CBS(Tm A) of 86 °C, CSE(Tm B) of 84 °C and β-actin (Tm C) of 90 °C. For each sample, the amount of both target and endogenous control (β-actin, a housekeeping gene) were determined. The typical amplification curves of real-time RT-PCR for CBS, CSE and β-actin mRNA are shown in Fig. 2. The amount of the target molecule was then divided by the amount of the endogenous reference, to obtain a normalised target value. The PCR products were also run on 1.5% agarose gel and visualised by ultraviolet light.

Figure 2  Cycles of CSE(A), CBS(B) and β-actin(C). For the four curves: control group(a), NaHS group(b), AR group(c) and PPG group(d). The vertical axis represents the degree of amplification by SYBR-Green fluorescence and the horizontal axis represents the number of amplification cycles. With the same cycle number, the groups have similar amplification of β-actin and CBS but different amplification of CSE.

The concentration of H$_2$S of Plasma, eotaxin of nasal lavage fluid, expression of mRNA of CSE and CBS of nasal mucosa. All data represent as mean ± S.D.*: Significantly different from the control group (p<0.05 and p<0.01, respectively). **: Significantly different from the AR group (p<0.05 and p<0.01, respectively).

Statistical analysis

All data were expressed as mean ± S.D. Statistical analyses of data were performed using ANOVA for multiple comparison and LSD for comparison among groups, and Pearson Correlation for the two-variable correlation analysis. P<0.05 was considered to be statistically significant.

Results

Concentration of H$_2$S in plasma

The blood H$_2$S level of the AR group was lower than that of the non-sensitised group (p<0.01). H$_2$S level increased significantly after being treated with H$_2$S donor NaHS, and decreased after PPG was administrated, as compared with AR group (p<0.05) (see Table 1). It indicated that down-regulation of H$_2$S level existed in AR, and NaHS increased H$_2$S level and PPG decreased it successfully.

Sneezing, nose rubbing and leukocyte infiltration

The results are shown in Fig. 3. Sneezing frequency and number of nose rubbings in sensitised AR group were significantly increased (p<0.01) as compared with a non-sensitised group, and increased further in PPG treated group as compared with AR group (p<0.05), but significantly decreased in NaSH treated group (p<0.05). In AR group, there was a significant increase of total cell count in NLF (p<0.01), especially eosinophils and neutrophils as compared with non-sensitised groups. Total cell count significantly increased after PPG treated, and decreased after NaHS treated (p<0.05), as compared with AR group. It indicated that NaHS increased the H$_2$S level but reduced the inflammatory response of allergy e.g. inhibited leukocyte infiltration in nasal mucosa, but PPG had the opposite effect on allergy.

Expressions of CBS and CSE by real-time RT-PCR

The cumulative data for mRNA expressions of CBS and CSE are presented in Table 1 and Fig. 4. CSE mRNA expression was down-regulated significantly in AR group as compared with control (p<0.05) and the expression was increased significantly after being stimulated by NaHS (p<0.05), and decreased significantly with PPG administration as compared with AR group (p<0.05). The expression of CBS in nasal mucosa was very weak and no significant changes of CBS mRNA levels were observed between groups (p>0.05).
Moreover, correlation between the level of H₂S and CSE mRNA expression level in nasal mucosa. Pearson Correlation was used to analyse the relationship between the level of H₂S and expression of CSE mRNA. There was a highly significant direct relationship between them (r = 0.87, P = 0.001).

Electrophoresis results showed that the order of CSE mRNA expression levels from high to low was control, NaHS, AR and PPG group (Fig. 5). Moreover, correlation between the level of CSE mRNA and concentration of H₂S was also analysed. There was a high significant direct relationship between them (r = 0.87, P = 0.001) (Fig. 6). It suggested that the level of H₂S was positively correlated with CSE of nasal mucosa through a concentration-dependent manner and that the NaHS and PPG regulated the level and might have a relationship with the expression of CSE of nasal mucosa in AR. The CBS of nasal mucosa perhaps had little effect on level of H₂S in AR.

**Discussion**

After nasal provocation with ovalbumin, the AR was evaluated from the occurrence of typical clinical symptoms with respect to nose and eyes irritation, like sneezing, conjunctival and nasal secretion. In comparison to saline, ovalbumin sensitisation increased sneezing frequency and numbers of nasal rubs. Nasal cellular infiltration (extravasation of leucocytes) is a characteristic hallmark of AR. Following nasal allergen challenge in sensitised guinea pigs, there was a significant increase in total cell count (p < 0.01) as compared with non-sensitised groups. Furthermore, both eosinophils and neutrophils were significantly induced. Sneezing frequency, number of nasal rubs, and total cell counts in nasal washings can be used as indices of allergic response.

This study was the first to show down-regulation of endogenous H₂S in sensitised AR guinea pigs. Previous studies had shown that gaseous transmitters, NO and CO, played important roles in the pathogenesis of AR. H₂S is a colourless and flammable gas with a small molecular weight, and now is increasingly recognised as a member of a growing family of “gasotransmitters”, together with its two counterparts, NO and CO. It was only recently that researchers came to understand H₂S as a novel gasotransmitter playing an important biological role, especially in airway inflammation such as in asthma, COPD, or lung injury.

H₂S is produced mainly by two pyridoxal-5’-phosphate-dependent enzymes responsible for the metabolism of L-cysteine, CBS and CSE. It should be noted that H₂S generation is closely associated with the catabolism of cysteine and methionine as well as with glutathione metabolism. Both CBS and CSE are responsible for the metabolism of methionine into cysteine, which is in turn used for the generation of H₂S, but the two enzymes differ in the specific mechanism of H₂S formation. CSE catalyses the conversion of cystine (a cysteine disulphide) to thiocysteine, pyruvate and ammonia, thiocysteine then enzymatically decomposes to cysteine and H₂S. The major mechanism of H₂S produced by CBS probably involves the condensation of homocysteine with cysteine to yield cystathionine, and H₂S is released during this reaction. Thus, the expressions of CBS and CSE had been identified in many human and other mammalian cells, including those from liver, kidney, brain, skin fibroblasts, and blood lymphocytes. In some tissues CBS and CSE are both needed for generation of H₂S, whereas in others only one enzyme is needed. Thus, it has come to be known that the expression of CBS and/or CSE is tissue specific. In nasal mucosa, more expression of CSE was found but not of CBS, and the mRNA...
expression of CSE was positively correlated with the concentration of H\textsubscript{2}S by concentration-dependent manner, so the CSE was maybe the major H\textsubscript{2}S-producing enzyme in nasal mucosa and it was positively correlated with the level of H\textsubscript{2}S in AR, because CSE mainly exists in vascular smooth muscle cells (SMC), and expressed in nasal mucosa might be attributed to the rich distribution of vascular SMC.

In order to investigate the influence of H\textsubscript{2}S level on symptoms of AR, NaHS was used as H\textsubscript{2}S donor. NaHS can be dissociated to Na\textsuperscript{+} and HS\textsuperscript{-} in solution, and then HS\textsuperscript{-} associates with H\textsuperscript{+} and produces H\textsubscript{2}S.\textsuperscript{24} In the experiment after NaHS treatment, H\textsubscript{2}S level was successfully up-regulated in plasma as compared with the AR group (p<0.05), and it alleviated the symptoms of AR. PPG was used as an inhibitor of H\textsubscript{2}S. Our observations had shown that PPG significantly attenuated the expression of CSE, and in the PGG group the level of H\textsubscript{2}S was decreased significantly as compared with the AR group. PPG can suppress the production of H\textsubscript{2}S by inhibited CSE, and symptoms of AR were aggravated after PPG treatment, accompanied by enhanced leukocyte adherence, leukocyte infiltration, perhaps with oedema formation. All these suggested that the level of H\textsubscript{2}S has a negative effect on symptoms of AR.

In mammalian tissues H\textsubscript{2}S may be a physiological regulator with its vascular effect possibly mediated by the opening of the K\textsuperscript{ATP} channel of vascular tissue, and H\textsubscript{2}S could also inhibit vascular SMC proliferation, and CSE mRNA was expressed mainly by the SMC of the vascular cells but not by the endothelial cells.\textsuperscript{27} A potentially critical role for CSE-derived H\textsubscript{2}S in allergic response is its ability to regulate airway smooth muscle associated with the tone of vascular. H\textsubscript{2}S can also suppress leukocyte adherence to the vascular endothelium and reduce leukocyte infiltration and oedema formation.\textsuperscript{28} We speculated that the down-regulation of the H\textsubscript{2}S/CSE pathway in the nasal mucosa of AR was associated with the change of blood flow. The release of H\textsubscript{2}S was decreased as CSE was suppressed by PPG leading to increased vasodilatation, and increased permeability of the nasal mucosa epithelium and vascular endothelium, and rapidly generated mediators of inflammation (leukotrienes, chemokines), associated with the allergic response, including rhinorrhea, mucosal oedema, neutrophil and eosinophil chemotactic effects. The level of H\textsubscript{2}S increased by NaHS had the opposite results with vasocostricter effects and was accompanied by the inhibition of inflammatory mediator release.\textsuperscript{29}

As mentioned above, H\textsubscript{2}S is also an important modulator of vascular tone like NO and CO, and plays an anti-oxidant role in inflammation.\textsuperscript{29} It should be noted that NO and CO may have direct vasorelaxation through endothelial cells.\textsuperscript{30} Immunohistochemistry researches show that NOS and NO, which are major rate-limited enzymes of NO and CO respectively, are mainly located in cytoplasm of endothelial cells.\textsuperscript{31} But the expression of H\textsubscript{2}S-generating enzyme was identified in vascular SMC, not in endothelium\textsuperscript{32} and it was shown that the vasorelaxant effect of H\textsubscript{2}S might mainly mediate by an interaction of the gas with smooth muscles.\textsuperscript{24} Thus, H\textsubscript{2}S seems to have a unique action mechanism among vasodilator gases in nasal mucosa. The gas signals among NO, CO and H\textsubscript{2}S may be a self-balancing regulation of endothelial cells and muscle cells in nasal mucosa of allergic inflammation. Vasorelaxation of H\textsubscript{2}S may be influenced by NO or CO, a recent study also suggests that low doses of H\textsubscript{2}S may induce vasoconstriction by scavenging endothelial NO.\textsuperscript{33} Perhaps the roles of H\textsubscript{2}S are regulated by NO or CO in the pathogenesis of AR, although further research is needed.

Conclusions

Our findings have shown that down-regulation of endogenous H\textsubscript{2}S pathway in AR, and the level of H\textsubscript{2}S was positively correlated with the expression of CSE in nasal mucosa. It indicated that endogenous H\textsubscript{2}S had latent roles in the pathogenesis of AR. Furthermore, the roles of H\textsubscript{2}S in pathogenesis of AR appear so complex, and more new lines of research are needed, and might have potential benefit for the investigation of AR.
