IRAK1 expression in bone marrow cells does not impact patient outcomes in myelodysplastic syndromes

Dear Editor,

Myelodysplastic syndromes (MDS) are myeloid neoplasms characterized by elevated rates of intramedullary apoptosis, associated with cytopenias in peripheral blood and with an increased risk of progression into acute myeloid leukemia (AML). The clinical course is highly heterogeneous, and different prognostic models have been designed to stratify patients into groups according to risk of disease progression and death. The only current curative treatment available is hematopoietic stem cell transplantation; however, the high treatment-associated morbimortality demands a need for the development of targeted therapies. Interleukin Receptor Associated Kinase-1 (IRAK1) is a protein that has intrinsic Toll-like receptor/Interleukin-1 Receptor (TLR/IL-1R)-induced kinase activity. IRAK1 binds and activates TNF receptor-associated factor 6 (TRAF6) and induces signaling through nuclear factor-κB (NF-κB). IRAK1 and TRAF6 are negatively regulated by miR-146a, which is frequently expressed at low levels in MDS. Rhyasen et al. described that the IRAK1 protein is overexpressed and highly phosphorylated in MDS patients. IRAK1 pharmacologic inhibition resulted in reduced cell proliferation in vitro and in amelioration of anemia in a human xenograft mouse model. Also, IRAK1 mRNA was overexpressed in CD34+ bone marrow cells from MDS patients, and high IRAK1 expression correlated with reduced overall survival in a cohort of 20 MDS patients.

In order to further investigate the role of IRAK1 mRNA expression as a potential prognostic marker in MDS, our aim was to characterize IRAK1 mRNA expression in a cohort of Brazilian MDS patients and to verify whether IRAK1 expression associates with clinical and laboratory features or impacts on event-free survival (EFS) and overall survival (OS) in MDS.

Bone marrow samples were collected from 14 healthy donors and 44 MDS patients followed up at the Hematology and Hemotherapy Center of the Universidade Estadual de Campinas between 2005 and 2013. Diagnosis was confirmed independently by three experts. Patients were untreated at the time of sample collection. The Institutional Review Board approved this research and all subjects provided written consent. For the purpose of this study, patients were classified according to the World Health Organization (WHO) 2008 classification and the revised international prognostic scoring system (IPSS-R). Patients’ characteristics are shown in Table 1.

RNA was extracted from total bone marrow cells using the Trizol reagent (Invitrogen, Carlsbad, CA, USA). The reverse transcription reaction was performed using the RevertAid First Strand cDNA Synthesis Kit (MBI Fermentas, St. Leon-Rot, Germany). Expression of IRAK1 mRNA was detected by Maxima Sybr Green qPCR master mix (MBI Fermentas, St. Leon-Rot, Germany) in an ABI 7500 Sequence Detection System (Applied Biosystems, Foster City, CA, USA) using specific primers for IRAK1 (FW: CCGTGTATGCTGTGAGAGG; RV: AGCCGTTCTGAGCAGTATG) and HPRT1 (FW: GAACGTTCTCGAGCAGATGTA; RV: TCCAGCAGTCAGCAAAGAAT). HPRT1 was used as the reference gene. The relative quantification value was calculated using the equation $$2^{-\Delta\Delta CT}$$.

A negative ‘no template control’ was included for each primer pair. The dissociation protocol was performed at the end of each run to check for non-specific amplification. Three replicas were run on the same plate for each sample. Statistical analyses were performed using Stata version 14.1 (Stata Corporation, College Station, TX, USA). For comparisons, Fisher’s exact test was used for categorical factors with two levels; the Mann-Whitney test was used for measured factors, as appropriate. Cox regression model was used to estimate the EFS and OS. EFS was defined as the time of sampling to the date of progression to high-risk MDS or AML with MDS related changes, date of death or last follow-up, and OS was defined from the time of sampling to date of death or last follow-up. A p-value < 0.05 was considered statistically significant.

We observed a significantly lower IRAK1 mRNA expression in total bone marrow cells from refractory anemia with excess blasts (RAEB)-1/RAEB-2 MDS patients compared to healthy donors (p-value = 0.04). There was no statistically significant difference in IRAK1 mRNA expression between refractory anemia (RA)/refractory anemia with ring sideroblasts (RARS)/refractory cytopenia with multilineage dysplasia...
In order to assess the impact of IRAK1 transcript levels on EFS and OS in MDS, patients were categorized according to tertiles or median. Highest tertile vs. lower two tertiles; individuals above median vs. individuals below median (all p-value > 0.05 – data not shown).

To evaluate the link between IRAK1 mRNA expression and survival, we used Cox regression. The relationship between IRAK1 mRNA expression and survival was analyzed by the Kaplan-Meier method (Figure 1). We also performed an analysis of the impact of IRAK1 mRNA expression on survival while controlling for other factors that might influence survival. This analysis included age at diagnosis, sex, and disease subgroup (MDS classification).

We used a univariate analysis to determine the impact of each variable on survival. Variables included in the analysis were age at diagnosis, sex, disease subgroup, and IRAK1 mRNA expression. A multivariate analysis was then performed to assess the independent impact of these variables on survival. The model included age at diagnosis, sex, disease subgroup, and IRAK1 mRNA expression. The results of the multivariate analysis indicated that IRAK1 mRNA expression was an independent predictor of survival (p-value = 0.002). Moreover, IRAK1 mRNA expression was also an independent predictor of OS (p-value = 0.001) and EFS (p-value = 0.003).

In conclusion, the deregulation of the IRAK1/TRAF6/NF-κB pathway may favor the development of MDS clones and the pharmacologic inhibition of IRAK1 might

HR: hazard ratio; 95% CI: 95% confidence interval; WHO: World Health Organization; RA: refractory anemia; RARS: refractory anemia with ringed sideroblasts; RCMD: refractory cytopenia with multilineage dysplasia; del(5q): MDS with isolated del(5q); RAEB-1: refractory anemia with excess blast-1; RAEB-2: refractory anemia with excess blast-2; IPSS-R: revised international prognostic scoring system.

Statistically significant p-values are highlighted in bold.

a Hazard ratios > 1 indicate that the increasing values for continuous variable or the first factor for categorical variable have poorer outcomes.
b Metaphase cytogenetics were not available in one patient.
c IRAK1 expression as continuous variable was included in univariate and multivariate analysis.

Figure 1 – Reduced IRAK1 levels in RAEB-1/RAEB-2 myelodysplastic syndromes (MDS). IRAK1 mRNA expression by quantitative polymerase chain reaction analysis in total bone marrow cells from healthy donors and patients with a diagnosis of MDS (all patients), refractory anemia (RA)/refractory anemia with ring sideroblasts (RARS)/refractory cytopenia with multilineage dysplasia (RCMD)/del(5q) MDS and refractory anemia with excess blasts (RAEB)-1/RAEB-2 MDS according to WHO 2008 classification. The HPRT1 gene was used as the reference gene and a healthy donor was used as a calibrator sample. Horizontal lines indicate medians. IRAK1 expression is significantly reduced in RAEB-1/RAEB-2 MDS patients when compared to healthy donors, as indicated (p-value = 0.04).
