Case Report

Simultaneous pulmonary thromboembolism and superior mesenteric venous thrombosis associated with hyperhomocysteinemia secondary to pernicious anemia-induced vitamin B12 deficiency

Leonardo Rodrigues de Oliveira*, Jordana Rafaela Fonseca

Introduction

The identification of conditions predisposing a patient to thrombosis is essential for the prevention and treatment of acute myocardial infarction, stroke, pulmonary embolism, and venous thrombosis. Accordingly, this knowledge should reduce the morbidity and mortality rates of patients with venous or arterial thrombosis.

Hyperhomocysteinemia is associated with an increased risk of arterial thrombosis (e.g. myocardial infarction, stroke, peripheral vascular disease) and may be associated with a higher risk of venous thrombosis. Therefore, clinical conditions normally associated with hyperhomocysteinemia, such as folic acid and vitamin B12 deficiencies, may also be associated with a higher risk of thrombosis.

The present report presents an unusual case of multiple and simultaneous venous thromboses in a patient with hyperhomocysteinemia secondary to pernicious anemia-induced vitamin B12 deficiency, who was treated with short-term anticoagulation therapy and vitamin B12 and folic acid supplementation.

Case report

A 58-year-old man was admitted to the emergency room owing to acute pain in the right hemiabdomen lasting three days. No fever, jaundice, or respiratory, urinary, or gastrointestinal changes had occurred. The patient’s comorbidities included Chagas disease (indeterminate chronic phase) and systemic arterial hypertension (regular losartan use). He had no history of tobacco or alcohol use, recent surgery, or prolonged immobilization (including long trips). A physical examination at the time of admission revealed normal findings, with no signs of peritoneal irritation.

Laboratory tests revealed discreet normocytic-normochromic anemia [hemoglobin (Hb): 12.0 g/L; mean corpuscular volume (MCV): 98.1 fL; and mean corpuscular hemoglobin: 33.1 pg] and increased serum lactate...
The association between hyperhomocysteinemia and pernicious anemia is an autoimmune condition that may co-occur with a loss of vitamin B12 absorption and consequent increase in the homocysteine levels. Several mechanisms have been proposed to link hyperhomocysteinemia with endothelial damage/dysfunction and consequently an increased risk of thrombosis, including decreased levels of nitric oxide, asymmetric dimethylarginine catabolism, vascular smooth muscle proliferation, platelet activation via increased thromboxane A2 biosynthesis, leukocyte activation, disruption of the hemostatic balance between coagulant and fibrinolytic, respectively.

Several mechanisms have been proposed to link hyperhomocysteinemia with endothelial damage/dysfunction and consequently an increased risk of thrombosis, including decreased levels of nitric oxide, asymmetric dimethylarginine catabolism, vascular smooth muscle proliferation, platelet activation via increased thromboxane A2 biosynthesis, leukocyte activation, disruption of the hemostatic balance between coagulant and fibrinolytic, respectively.

Dietary restriction, nitric oxide abuse, malabsorption states (e.g., pernicious anemia, celiac disease, Helicobacter pylori infection) and adverse effects of various drugs (e.g., metformin, omeprazole, oral contraceptives) are known causes of vitamin B12 deficiency. Pernicious anemia is an autoimmune condition that may co-occur with a loss of vitamin B12 absorption and consequent increase in the homocysteine serum levels. Accordingly, patients with pernicious anemia would be expected to have a higher incidence of thrombosis.

The present case is peculiar because it

Discussion

Venous thromboembolism (VTE) is an important cause of intra- and extra-hospital morbidity and mortality. Thus, it is essential to identify the factors associated with an increased thrombotic risk during the establishment of measures to prevent and treat thromboses.

Hyperhomocysteinemia, although a risk factor for thrombosis, is more consistently associated with arterial events such as stroke, myocardial infarction and peripheral vascular disease. The association between hyperhomocysteinemia and venous thrombosis remains highly controversial. Previous studies have reported two- to three-fold higher risks of VTE among patients with hyperhomocysteinemia. Further, a meta-analysis of 24 retrospective and three prospective epidemiological studies reported a modest, although real, association between hyperhomocysteinemia and VTE (27% increase in risk in the prospective studies, and 60% increase in retrospective studies for every 5-μmol/L increase in serum homocysteine levels). Moreover, an increased incidence of venous thrombosis has been observed among Brazilian patients with hyperhomocysteinemia.

Hyperhomocysteinemia is the result of defective renal homocysteine excretion or deficiencies in enzymes or cofactors associated with pathways that convert homocysteine to methionine or cysteine via remethylation or transsulfuration, respectively.
In conclusion, studies of the intrinsic relationship between homocysteine, vitamin B12 and venous thrombosis remain necessary. In particular, studies of hyperhomocysteinemia in patients with unexplained venous thrombosis should be conducted systematically, with the intent to identify the etiology and provide prophylactic interventions for secondary VTE. Finally, the absence of anemia and macrocytosis as signs of vitamin B12 or of folic acid deficiency should not discourage studies on hyperhomocysteinemia.
