Organic solvent tolerant lipase
Thermostable lipase

A B S T R A C T
The purpose of this study was to isolate, purify and optimize the production conditions of an organic solvent tolerant and thermostable lipase from Acinetobacter sp. AU07 isolated from distillery waste. The lipase production was optimized by response surface methodology, and a maximum production of 14.5 U/mL was observed at 30 °C and pH 7, using a 0.5% (v/v) inoculum, 2% (v/v) castor oil (inducer), and agitation 150 rpm. The optimized conditions from the shake flask experiments were validated in a 3L lab scale bioreactor, and the lipase production increased to 48 U/mL. The enzyme was purified by ammonium sulfate precipitation and ion exchange chromatography and the overall yield was 36%. SDS-PAGE indicated a molecular weight of 45 kDa for the purified protein, and Matrix assisted laser desorption/ionization time of flight analysis of the purified lipase showed sequence similarity with GDSL family of lipases. The optimum temperature and pH for activity of the enzyme was found to be 50 °C and 8.0, respectively. The lipase was completely inhibited by phenylmethylsulfonyl fluoride but minimal inhibition was observed when incubated with ethylenediaminetetraacetic acid and dithiothreitol. The enzyme was stable in the presence of non-polar hydrophobic solvents. Detergents like SDS inhibited enzyme activity; however, there was minimal loss of enzyme activity when incubated with hydrogen peroxide, Tween 80 and Triton X-100. The kinetic constants (Km and Vmax) revealed that the hydrolytic activity of the lipase was specific to moderate chain fatty acid esters. The Vmax, Km and Vmax/Km ratio of the enzyme were 16.98 U/mg, 0.51 mM, and 33.29, respectively when 4-nitrophenyl palmitate was used as a substrate.

Introduction

Lipases (EC 3.1.1.3) are enzymes that cleave ester bonds in lipidic substrates. In the presence of water, they catalyze the hydrolysis of triglycerides to form monoglycerides, diglycerides, glycerol and free fatty acids. Lipases are serine hydrolases and are active at the lipid-water interface. They are ubiquitous in nature and are found in a variety of plants, animals and microorganisms. Most bacterial lipases are
secreted extracellularly and are versatile biocatalysts that carry out a variety of reactions viz. hydrolysis, esterification, transesterification, inter esterification, acidolysis, and aminolysis. Lipases utilize a wide spectrum of substrates, and some of them are stable at extreme temperature, and pH conditions and in organic solvents. They are used as catalysts for reactions in reduced water environments. Frequently, the substrates of lipases are insoluble in aqueous solution. Hence, conducting the reactions in organic solvents can improve the dissolution of substrates and increase substrate availability, in addition to aiding in the easy separation of enzymes from substrates or products.

Lipolytic strains isolated from industrial effluents show potential utility in biodegradation and bioremediation. The biofilm formed by lipase secreting organisms can be used to degrade fats and oils. Therefore, we have produced, purified and biochemically characterized a lipase isolated from Acinetobacter sp. AU07. We also optimized the physical conditions by employing response surface methodology (RSM) to improve lipase production.

**Materials and methods**

**Chemicals**

Enzyme substrates (4-nitrophenyl esters) and inhibitors were procured from Sigma (St. Louis, USA). Chemicals for media preparation were purchased from Hi-Media (Mumbai, India). The ion-exchange chromatography sorbent diethylaminoethyl (DEAE) Sepharose fast flow was purchased from GE Health care. All chemicals used were of analytical grade.

**Isolation and screening of lipase producing organisms**

The lipase producing organisms were isolated from a distillery unit. The liquid sample (1 mL) was suspended in 9 mL sterilized water, serially diluted and spread on selective medium containing sesame oil as the sole carbon source and incubated at 37 °C for 24 h. This selective medium contained 2.0 g/L peptone, 5.0 g/L NaCl, 20 (v/v) sesame oil (emulsified with 0.01% Triton X-100), and 15.0 g/L bacteriological agar.

To screen for lipase production, individual bacterial colonies were streaked onto plates containing tributyrin 1.25 g/L (emulsified with 0.01% Triton X-100) and 15 g/L bacteriological agar. The plates were incubated at 37 °C for 24 h, and colonies that formed a zone of clearance were lipolytic positive strains. The thirteen positive isolates were further screened for maximal secretion of extracellular lipase by assaying the lipase activity in liquid culture using 4-nitrophenyl palmitate as a substrate at 37 °C. The Acinetobacter sp. AU07 strain, which showed the highest activity, was selected for further study. This strain was maintained in glycerol stocks (50%, v/v) and stored at −20°C.

**Identification of the lipolytic strain**

The taxonomy of the isolated strain was examined using Bergey's Manual of Determinative Biology and confirmed by 16S rDNA sequencing. A BLAST analysis of the 16S rDNA sequence identified the strain as Acinetobacter sp. AU07. The 800 bp 16S rDNA gene sequence of the Acinetobacter sp. AU07 strain has been submitted to the GenBank database, with the accession number HQ914215.

**Optimization of media and culture conditions for lipase production by response surface methodology**

One-factor-at-a time strategy

The production of lipase by Acinetobacter sp. AU07 was performed using different vegetable oils as inducers viz. castor oil, palm oil, coconut oil, sesame oil, and olive oil at (1%, v/v), with 1% inoculum at 30 °C for 20 h in a rotary shaker (150 rpm). The media containing oils were emulsified with 0.25% gum acacia and were adjusted to pH 7.0. The individual effects of pH, temperature and inducers were monitored and optimized. The cell-free supernatant was recovered by centrifugation at 12,500 × g for 10 min at 4 °C and used to determine extracellular lipase activity.

The nutrient medium containing castor oil enhanced lipase secretion and was therefore selected for further optimization of lipase production by central composite design (CCD). response surface analysis. The variables utilized for RSM were as follows: temperature, pH, agitation, inducer concentration, and inoculum volume. All five variables were tested at three levels and designated as −1, 0, +1. The data from CCD were analysed by the least squares method. A total of 26 experiments were conducted. The response values (Y) in each trial were the average of the three replicates. The statistical software package 'Design Expert' software (Version 8.0, Stat-Ease Inc., Minneapolis, USA) was used to analyse the experimental designs.

**Spectrophotometric assay for lipase using 4-nitrophenyl palmitate**

The lipase activity was measured spectrophotometrically using 4-nitrophenyl palmitate (4-NPP) as the substrate. First, 400 μL of the enzyme was equilibrated with 50 μL of 1 M Tris–HCl buffer (final concentration 50 mM), and diluted with 530 μL sterile water. Next, 20 μL of 4-NPP (final concentration 1 mM) was added, and the reaction was incubated at 30°C for 10 min. The concentration of released 4-nitrophenol was measured at 410 nm. The protein content was determined by Bradford’s method using the Bio-Rad assay reagent, with bovine serum albumin (BSA) as a standard.

**Purification of lipase**

The culture was grown for 16 h and centrifuged at 12,500 × g for 15 min at 4°C. To precipitate the proteins the culture supernatant was added with solid ammonium sulfate (60% saturation) with continuous stirring and incubated at 4°C for 24 h. After incubation, the sample was centrifuged at 4°C for 15 min at 12,500 × g, and the resulting pellet was dissolved in 10 mM Tris–HCl buffer (pH 8.0) and dialyzed with the same buffer for 12 h at 4°C. The dialyzed protein sample was then loaded on-to a DEAE Sepharose anion exchanger, which had been pre-equilibrated with 20 mM Tris–HCl and eluted with a buffered NaCl (0.1–1M) concentration gradient. The lipase containing fractions were pooled and dialyzed with 10 mM
Tris–HCl buffer. The resulting dialyzed protein sample was then lyophilized.

**RP-HPLC analysis of purified lipase**

The purity of the enzyme was analysed by RP-HPLC using an Agilent 1100 HPLC system with a C-18 column (Zorbax C-18, 4.6 mm × 250 mm i.d., 5 μ particle size; Agilent technologies). The column was eluted with 0.1% (v/v) trifluoroacetic acid (TFA) in water and 0.1% (v/v) TFA in acetonitrile. The bound proteins were eluted with an increasing gradient of 2 to 100% acetonitrile for 40 min at a flow rate of 1 mL/min.

**Molecular weight determination by SDS-PAGE**

The lipase purified by ion exchange chromatography was subjected to SDS-PAGE (4% and 10%, v/v acrylamide stacking and separating gel). Next, the resulting gel was stained with Coomassie Brilliant Blue, and the molecular weight was determined by comparing the protein band with a standard protein marker containing mixtures of phosphorylase b (97 kDa), albumin (66 kDa), ovalbumin (45 kDa), carbonic anhydrase (30 kDa), trypsin inhibitor (20 kDa) and α-lactalbumin (14 kDa).

**Mass spectrometric sequence analysis of lipase from Acinetobacter sp. AU07**

MALDI-TOF MS is a sensitive technique used to analyse protein sequences by screening the masses of peptides and small proteins. By measuring the masses of peptides, it is possible to determine the sequence of the protein. The purified lipase was excised from the SDS-PAGE gel and subjected to proteolysis by trypsin, and the resulting peptides were analysed using MALDI-TOF. The mass of the residues of the purified lipase was obtained and used to search against the MASCOT database for peptide mass fingerprinting.

**Biochemical characterization of purified Acinetobacter sp. AU07 lipase**

**Effect of temperature on lipase activity and stability**

The optimum temperature for lipase activity was measured by incubating aliquots of purified enzyme with 4-nitrophenyl palmitate (4-NPP) (1 mM final concentration) and 20 mM sodium-phosphate buffer at temperatures ranging from 30 to 80 °C for 10 min, and the relative activity was determined following incubation.

The thermal stability of the lipase was measured by incubating aliquots of purified enzyme at 40 °C, 50 °C, 60 °C and 70 °C for 5 h, after which the residual activity was determined using the following equations:

\[
\ln(A) = \ln(A_0) - k_d t
\]

where \(A_0\) is the initial activity, \(A\) is the residual activity in time \(t\) and \(k_d\) is first-order deactivation rate coefficient:

\[
t_{1/2} = \frac{\ln(0.5)}{k_d}
\]

From Eq. (1), the thermal deactivation profiles were determined, and the respective deactivation rate \(k_d\) estimated. From Eq. (2), the half-life \(t_{1/2}\) of the biocatalyst was estimated from the previously determined \(k_d\) value.

**Effect of pH on lipase activity and stability**

The optimal pH was determined by assaying the purified enzyme at different hydrogen ion concentrations using the following buffers: citric acid/sodium acetate (pH 3.0–5.0), sodium phosphate (pH 6.0–7.5), Tris–HCl (pH 7.0–9.0), glycine–NaOH (pH 9.0–10.0) and phosphate–NaOH (pH 11.0).

For the pH stability studies, the purified enzyme was incubated with the respective buffers (50 mM) for 1 h at 30 °C, and then the residual activity was determined.

**Effect of organic solvents on lipase stability**

The purified lipase was incubated with 30% (v/v) organic solvent at 30 °C with constant agitation at 150 rpm for 4 h. Aliquots of the suspended enzyme were taken at different intervals, and the solvent was evaporated. The enzyme activity was then measured at 30 °C and pH 8.0. The stability of the lipase was calculated by comparing the residual activity with the control, which was incubated without the organic solvent.

**Effect of metal ions on lipase activity**

Various metal salts (ZnCl₂, MgSO₄·7H₂O, FeCl₃, CaCl₂·2H₂O, AgNO₃, MnSO₄·H₂O) were added to the purified lipase at concentrations of 2 mM, 5 mM, and 10 mM and incubated at 30 °C for 30 min. The relative activity of the enzyme was measured as the change in the activity of the enzyme in the presence of metal salts when compared to the enzyme activity without metal salts.

**Effect of inhibitors, detergents, and oxidizing agent on lipase stability**

The stability of the purified lipase in the presence of inhibitors, detergents and oxidizing agent was evaluated by incubating the purified lipase with the inhibitors—DTT, EDTA and PMSF at a final concentrations of 2 mM, 5 mM and 10 mM; the detergents—Tween 80, Triton X-100, SDS at a final concentration of 0.25%, 0.5% and 1%; and an oxidizing agent—H₂O₂ at a final concentration of 0.5%, 1%, 1.5% and 2%. The incubated enzyme (without inhibitors, detergents and oxidizing agent) was used as a reference to calculate the relative activity.

**Determination of lipase kinetics using different substrates**

The hydrolytic activity of Acinetobacter sp. AU07 lipase was investigated using different substrates, such as 4-nitrophenyl butyrate (4-NPB), 4-nitrophenyl laurate (4-NPL), 4-nitrophenyl myristate (4-NPM) and 4-nitrophenyl palmitate (4-NPP), at various substrate concentrations (0.2–2 mM). The Michaelis–Menten enzyme kinetic constants \(V_{max}\) and \(V_{max}\) were determined from the Lineweaver–Burk and Woolf–Hanes plots.
Results and discussion

Isolation and identification of bacteria producing extracellular lipase

The bacterial strains that were isolated from distillery waste were screened for lipase secretion by selection on tributyrin agar plates. The AU07 strain that showed a larger zone of clearance around the colony was selected for further studies. The morphological and biochemical characterization revealed that the AU07 strain is aerobic, gram negative and non-motile. The strain was confirmed as Acinetobacter sp. AU07 by 16S rDNA sequencing which is in accordance with Bergey’s Manual of Determinative Biology.

Optimization of culture conditions for lipase production by response surface methodology

A maximal lipase activity of 331.16 U (specific activity of 38.64 U/mg) was obtained by culturing the bacterium at 30 °C and pH 7.0 for 16 h. The lipase production reached a maximum during the stationary phase and then gradually decreased. The fermentation time to obtain maximum lipase activity is similar to that of lipase production by Acinetobacter sp. BK44 where maximal lipase activity occurs after 12 h of incubation.13

Though the lipase production from this strain is constitutive, the incorporation of oils in the medium increased the enzyme production.
Fig. 1 – Response surface plots of the impact of various factors on optimal production of the AU07 lipase. Each figure depicts the impact of specific factors on lipase production. The variables investigated were temperature, pH, agitation, inducer concentration, and inoculum volume. (A) Temperature and pH, (B) temperature and agitation, (C) temperature and inducer, (D) temperature and inoculum volume, (E) pH and agitation, (F) pH and inducer, (G) pH and inoculum volume, (H) agitation and inducer, (I) agitation and inoculum volume, and (J) inducer and inoculum volume.

similar to those of Acinetobacter radioresistens\textsuperscript{20} and Acinetobacter calcoaceticus LP009.\textsuperscript{21} Our standardized conditions gave an optimum lipase production of 14.5 U/mL (Fig. 2A).

The model predicted a maximum lipase production of 16.08 U/mL at 34 °C, and pH 7.8, with castor oil as the inducer (2.3%, v/v), at an inoculum volume (0.44%, v/v), and with agitation at 199 rpm. To validate the predicted response, the lipase production was tested experimentally under optimal culture conditions, and the maximum lipase activity was 15.84 U/mL. The lipase production from this strain

The response surface quadratic model was analyzed by ANOVA (Table 2), and used to generate a quadratic equation for lipase activity ($Y$). The adjusted $R^2$ (adj. $R^2 = 0.9816$) is high and confirmed the model is significant. Additionally, the statistical coefficients confirmed that the model is significant and can be applied to increase lipase production. The production of lipase increased to 48 U/mL when cultivated in a 3L bioreactor under controlled conditions (Fig. 2B).

$$Y(\text{Lipase activity}) = +14.70 + 1.12 \times A + 0.90 \times B + 0.23 \times C$$
$$+ 0.71 \times D + 2.44 \times E + 1.19 \times A \times B$$
$$+ 0.96 \times A \times C + 0.70 \times A \times D - 0.92 \times A \times E$$
$$+ 1.39 \times B \times C + 1.20 \times B \times D - 0.73$$
$$\times B \times E + 1.66 \times C \times D - 1.38 \times C$$
$$\times E - 1.44 \times D \times E - 2.60 \times A^2 - 2.18 \times B^2$$
$$- 0.93 \times C^2 - 1.59 \times D^2 - 1.88 \times E^2$$

The equation above gives the relationship between lipase activity and the tested variables, where $A$ is the temperature, $B$ is pH, $C$ is agitation, $D$ is inducer concentration, and $E$ is inoculum volume.

### Purification of lipase

The Acinetobacter sp. AU07 lipase (ASL) was partially purified by ammonium sulfate precipitation (30–60% saturation) and further purified to homogeneity by anion exchange chromatography. The lipase was successfully purified from cell-free crude supernatant with an overall yield of 36.04%, with a 2.2 fold purification and a specific activity of 83.47 U/mg. The purification results are summarized in Table 3. The Acinetobacter sp. AU07 lipase was eluted in an increasing gradient of NaCl (0.1–1 M). The maximal lipase activity was obtained in the fraction eluted with 600 mM of NaCl, indicating the strong binding of the protein to the ion-exchange resin. The purity of the enzyme was analyzed by RP-HPLC. The lipase was eluted as a single peak with a retention time of 20.537 min as shown in the Supplemental Fig. S3.

#### SDS-PAGE of ion-exchange purified lipase

The purified enzyme resolved into a single band on an SDS-PAGE gel (Fig. 3) had an estimated molecular weight of 45 kDa, which is the same as the A. radioresistens CMC-1 lipase. 23

#### Mass spectrometric sequence analysis of the lipase from Acinetobacter sp. AU07

The lipase in this study has 55% homology to the lipase from A. calcoaceticus PHEA-2 followed by the lipases from Acinetobacter pittii and Acinetobacter baumannii. The partial amino acid sequence is shown in Fig. 4. The molecular mass and the isoelectric point (pI) were predicted to be 41.196 kDa and 7.14, respectively. The peptide masses and the matching amino acid sequences of peptides are listed in the Supplemental Fig. S4.

The activity of a variety of lipases primarily depends on the catalytic triad typically formed by Ser, His, and Asp...

A two-step purification of the lipase by ammonium sulfate (60% saturation) and ion exchange chromatography (0.1–1 M NaCl elution). The assay was performed by incubating the enzyme at 30 °C for 10 min with 1 mM 4-NP as the substrate. The protein concentration was estimated by the standard Bradford assay procedure. Each value is the average of three replicates.

| Table 4 – Half-life and thermal deactivation constants at different temperatures. |
|-----------------------------------|-------------------|-------------------|

The half-life and thermal deactivation constants were determined by incubating aliquots of pure enzyme at various temperatures for 5 h, after which, the residual enzyme activity was determined.

Biochemical characterization of purified Acinetobacter sp. AU07 lipase

Effect of temperature on activity and stability of lipase

The optimum temperature for lipase activity was 50 °C (Fig. 5A), whereas approximately 75% and 25% activity were observed at 60 °C and 70 °C, respectively. The optimum temperature for lipase activity was similar to that of lipase from A. calcoaceticus LP009. The stability of the lipase at different temperatures was determined by incubating the enzyme at different temperatures for 5 h and assaying the enzyme at 50 °C. After 5 h, the enzyme retained 78% activity at 40 °C and 72% activity at 50 °C (Fig. 5B), which demonstrates that the enzyme is thermo stable. A linear increase in the deactivation constants (k_d) was observed when the temperature was increased from 40 °C to 60 °C. The half-life of the enzyme was 1 h 38 min at 40 °C, 1 h 9 min at 50 °C and 1 h and 7 min at 60 °C. The corresponding thermal deactivation constants (k_d) and half-life (t₁/₂) of the purified lipase are shown in Table 4.

Effect of pH on activity and stability of lipase

Most of the lipases from Acinetobacter sp. are alkali stable, losing their activity at low pH. This could be due to the loss of the coordinating metal ion Ca²⁺ metal ion from the active site. This triad was present in the isolated Acinetobacter sp. lipase sequence (Supplemental Fig. S5). Partial amino acid sequencing confirmed that the enzyme isolated in this study possesses the characteristics of the lipase enzyme family.

Fig. 4 – Partial amino acid sequence of the isolated lipase showing homology with Acinetobacter calcoaceticus (55% identity).
site at low pH. The purified lipase in this study showed the highest activity at pH 8.0 which is similar to the Acinetobacter sp. CR9 lipase and the Acinetobacter baileyi lipase. The A. radiotolerans CMC-1 lipase had a pH optima at 10.5, whereas, A. calcoaceticus 1–7 had a pH optima of 9. In contrast, the lipases from A. calcoaceticus LP009 and Acinetobacter sp. had pH optima of 7 and 6 respectively. ASL presented a relative activity of 65% at pH 9, 26% at pH 10, and only 11% at pH 11. The activity was not reduced significantly after incubation for 1 h at 30 °C (Fig. 5C).

Effect of organic solvents on lipase stability
The stripping of water from an enzyme primarily occurs in the presence of polar solvents and to a lesser degree in the presence of hydrophobic solvents determined by logp values. For instance, methanol desorbed approximately 60% of the water bound to the enzyme, while hexane only desorbed 0.5%. Solvents with high logp values cause less inactivation of enzyme than solvents with low logp values. Many researchers have previously reported the solvent stable nature of lipases, thus the stability of Acinetobacter sp. AU07 lipase in different solvents was studied (Table 5). The polar solvents (low logp) reduced the enzyme activity, whereas the non-polar solvents (higher logp) increased the enzyme activity. Among the polar solvents, DMSO increased the activity 1.9 fold. Toluene a non-polar solvent, increased the activity 3.5 fold when incubated for 2 h and 2.8-fold when incubated for 4 h. When incubated for 4 h each at 30 °C, other non-polar solvents also increased the activity considerably, viz., n-hexane 1-fold, dichloromethane 0.4-fold, and n-heptane 0.7-fold.

Effect of metal ions on lipase activity
Metal ions decreased the activity of the enzyme. The lipase retained only 3% of its initial activity with a 10 mM Zn$^{2+}$...
The enzyme was pre-incubated for 2 and 5 h with different organic solvents (30%, v/v) while shaking (150 rpm) at 30 °C and assayed under standard assay conditions. The stability of the lipase was calculated by comparing the residual activity with that of the control, which was incubated without the organic solvent and whose enzyme activity was taken as 100%. The standard deviation for all the values is ±5.0%.

The enzyme was incubated with different detergents on the Acinetobacter sp. AU07 lipase activity. The enzyme was incubated with different inhibitors at 30 °C for 1 h, and the enzyme activity was assayed under standard assay procedure conditions. The enzyme incubated without inhibitors was used as a reference to calculate the relative activity. Each value presented here is an average of three replicates.

Effect of inhibitors, detergents, and oxidizing agents on lipase activity
Phenyl methylsulphonyl fluoride (PMSF: an inhibitor of serine lipase) inhibited the lipase activity (88% inhibition at 2 mM concentration). Similar results were observed in the lipases from *A. radioresistens* CMC-1 and *Bacillus stearothermophilus* PT₄₀ suggesting the involvement of a serine residue in the active site. There was minimal inhibition by EDTA and DTT (Fig. 6). The decrease in the enzyme activity in the presence of metal ions and the absence of inhibition of the enzyme activity by EDTA indicate that metal ions are not required for the lipase activity. These results suggest that this lipase may be a member of serine-enzyme family. The effect of detergents such as SDS, Tween 80 and Triton X-100 on the enzyme activity were studied. SDS inhibited the enzyme activity; however, there was minimal loss in enzyme activity when incubated with 0.25 mM Tween 80 or Triton X-100 (Table 7). Oxidizing agents (hydrogen peroxide) had minimal effect on the enzyme activity, and the enzyme retained 94% (at 0.5 mM) and 73% (at 2 mM) of its enzyme activity, respectively.

**Determination of lipase kinetics using different substrates**
The kinetic parameters (κₘ and V max) of hydrolysis of different fatty acid esters were determined. The κₘ was higher for 4-nitrophenyl butyrate (short fatty acid esters), and low κₘ values were obtained for 4-nitrophenyl laurate, 4-nitrophenyl butyrate, and 1-naphthyl butyrate.
myristate and 4-nitrophenyl palmitate (moderate chain length fatty acid esters) indicating that the Acinetobacter sp. AU07 lipase is more specific to soluble fatty acid esters of moderate chain lengths. These results are consistent with Acinetobacter baumannii BDS lipase. A low Kₘ value indicates the enzyme has a high affinity for a substrate, whereas a high Kₘ value indicates a low affinity. The comparison of kinetic constants (Kₘ and Vₘₐₓ) obtained for various substrates (4-nitrophenyl esters) suggest that the hydrolytic activity of this lipase was specific to moderate chain fatty acid esters. This lipase was found to have a lower Kₘ value for 4-Nitrophenyl laurate when compared with the other substrates. This suggests that the lipase has a higher affinity towards 4-nitrophenyl laurate.

The Vₘₐₓ values for 4-NPL, 4-NPM and 4-NPP were high and were similar in range (Table 8). The Vₘₐₓ/Kₘ ratio was different for all substrates used, but for moderate and long chain fatty acid esters, it exceeded the ratio for p-NPB. The Kₘ and Vₘₐₓ values determined by the Lineweaver–Burk and Woolf–Hanes plots for the different substrates are shown in Supplemental Fig. S6.

**Conclusion**

A thermostable organic solvent tolerant lipase from Acinetobacter sp. AU07 has been purified and characterized biochemically. The production was improved by optimizing the cultivating conditions using response surface methodology. The purified enzyme showed several important properties such as activity in alkaline pH, resistance to surfactants and oxidizing agents that would prove useful in industrial applications and in the detergent and pharmaceutical industries. The biofilms of the lipase secreting Acinetobacter sp. AU07 may be used for bioremediation to treat waste water contaminated with oils. The thermostable and organic solvent tolerant nature of the lipase can be used to perform synthetic reactions in the presence of organic solvents and at high temperatures.
