Chest Pain as the Predominant Symptom in Myocarditis in Children

_Dolor precordial como forma de presentación de la miocarditis en niños_

To the Editor,

Acute myocarditis is an inflammatory process of the myocardium that most frequently affects children and young adults. Its forms of presentation include heart failure, arrhythmia, syncope, and sudden death.¹ One of the most commonly involved viruses is Parvovirus B19,² which has a special tropism for endothelial cells and has been associated with episodes of chest pain and isolated diastolic dysfunction.²³ Noninfectious causes include giant cell myocarditis and eosinophilic myocarditis. The definitive diagnosis is histological, but magnetic resonance imaging (MRI) is very useful as a noninvasive diagnostic method.⁵

We report 3 patients with precordial pain, electrocardiographic changes and elevation of markers of myocardial damage. The differential diagnosis included acute myocarditis and myocardial ischemia. The analytic study ruled out other causes of chest pain, such as familial hypercholesterolemia. The diagnosis was made with MRI.

The first patient was a 10-year-old girl diagnosed with acute lymphoblastic leukemia with reactive eosinophilia. Her blood tests showed leucocytosis with eosinophilia. During the course of the disease, she showed a reduction in level of consciousness, and brain MRI showed lesions compatible with vascular disease. A few days later, she experienced precordial pain, electrocardiographic changes with ST depression in LII, LIII, V₁-V₄ and T-wave inversion in all leads, and an increase in cardiac enzyme levels (maximum values: troponin T, 6.7 μg/L; creatine kinase-MB fraction, 38 μg/L). An echocardiogram showed normal coronary artery anatomy and increased left ventricular thickness (septum 10 mm [Z-score=2.26] and posterior wall 10 mm [Z-score=2.26]) with normal systolic function. The MRI scan showed inflammatory infiltrates in the free wall of the left ventricle and the interventricular septum. The clinical picture was considered to be that of eosinophilic myocarditis. Both the neurological and the cardiac pictures resolved by treating her underlying disease.

The second patient was a 14-year-old boy who presented to the emergency department with intense precordial pain, which was oppressive, unrelated to exercise and unaffected by postural changes. At admission, the patient had a fever of 38 °C. The electrocardiogram showed ST elevation in the lower leads (LII, LIII and aVF) and V₁ and V₂ (Fig. 1). Troponin T was 2.8 μg/L and

left ventricle, compatible with acute myocarditis. Polymerase chain reaction testing of blood and nasopharyngeal aspirate was negative for viruses. The patient's course was favorable.

Precordial pain is a presentation of acute myocarditis and, although uncommon in children, should be included in the differential diagnosis.

The usefulness of MRI in these patients has been previously reported. The clinical course is usually favorable and the most commonly described causative agent is Parvovirus B19. In the cases reported here, the diagnostic utility of MRI should be emphasised as it allowed catheterization to be avoided in our patients. It should be performed as an emergency procedure and, if inconclusive, a coronary angiography should be conducted to rule out coronary disease.

**Fenestration Closure After Fontan Surgery. Contributions of Percutaneous Interventionism**

**Cierre de fenestración tras la cirugía de Fontan. Aportaciones del intervencionismo percutáneo**

**To the Editor,**

The Fontan procedure is the final step in surgery for patients with a single ventricle. The hemodynamic changes that occur after the procedure can have a negative impact on the immediate outcome due to a sudden increase in pulmonary artery pressure. Fenestration of the Fontan circuit during surgery is therefore a common procedure in high-risk patients, although systemic saturation may decrease as a result. The development of percutaneous implantation devices has enabled fenestration closure without the need for further surgery when hemodynamic conditions allow.²,³

Here, we analyze our experience of percutaneous closure of fenestrations in the extracardiac circuit after the Fontan procedure, taking into account the properties of the new occlusion devices available. In addition, we study the changes in pulmonary artery...
