Familial Left Ventricular Noncompaction Associated With a Novel Mutation in the Alpha-cardiac Actin Gene

Miocardiopatía no compactada familiar asociada con una mutación nueva en el gen de la alfa-actina cardiaca

To the Editor,

Left ventricular noncompaction (LVNC) is characterized by multiple prominent ventricular trabeculations and deep intertrabecular recesses. A familial background is found in 18% to 50% of adults and the estimated prevalence in echocardiographic studies is 0.014% to 1.300%. Its genetic bases are heterogeneous, with only two reported mutations in the alpha-cardiac actin gene (ACTC1): ACTC1M271V and ACTC1E101K with additional apical hypertrophic cardiomyopathy, restrictive filling, and septal defects. As in other inherited familial conditions, the finding of a pathogenic mutation can be very valuable when screening at-risk relatives.

Herein we present a family with LVNC caused by the novel heterozygous ACTC1I289T mutation, which exhibited different clinical features and courses in the affected family members, namely isolated LVNC, LVNC associated with atrioseptal defect, and restrictive cardiomyopathy associated with atrioseptal defect.

A 9-month-old girl underwent heart transplantation in another hospital because of a restrictive cardiomyopathy with dilated atria, depressed left ventricular ejection fraction, and an associated small ostium secundum atrioseptal defect (proband, Figure, IV:1). At hospital discharge, the presence of a previously unsuspected LVNC was reported in the macroscopic evaluation of the heart. No histologic evaluation was carried out and no samples from the explanted heart were kept for further examination. A comprehensive workup, approved by the local research ethics committee, was offered to her first-degree relatives and the family tree was accordingly expanded. This evaluation included electrocardiogram, echocardiography, and blood sampling for genetic studies. Cardiac magnetic resonance imaging, exercise testing, and Holter-electrocardiogram were performed at cardiologist discretion. LVNC was defined following Jenni’s (telesystolic noncompacted/compacted myocardium > 2 by echocardiography) and/or Petersen’s criteria (telediastolic noncompacted/compacted > 2.3 by cardiac magnetic resonance imaging).

Sanger sequencing (MYH7, myosin binding protein C3, Nkx2.5, and ACTC1 genes) was performed in genomic DNA of the maternal

**Figure.** Familial pedigree. ACTC1, alpha-cardiac actin gene; LVNC, left ventricular noncompaction; LVH, left ventricular hypertrabeculation; MI, myocardial infarction; NE, not evaluated; OS-ASD, ostium secundum atrioseptal defect; RCM, restrictive cardiomyopathy. Circles denote females, squares males. Red symbols represent affected individuals. *Macroscopic evaluation at heart transplantation.

Improvement in Hemodynamics and Contractility With Multipoint Left Ventricular Pacing in Cardiac Resynchronization Therapy

Mejoría hemodinámica y de la contractilidad con la estimulación multipunto del ventrículo izquierdo en la terapia de resincronización cardíaca

To the Editor,

Heart failure is a leading cause of morbidity and mortality in Western countries. Biventricular pacemakers have been used to treat heart failure since the 1990s. Over the last decade, randomized studies have demonstrated the benefit of cardiac resynchronization therapy (CRT) and helped to establish its indications. This therapy has been shown to increase survival and decrease hospitalizations in patients with heart failure, left ventricular (LV) dysfunction, and prolonged QRS, in particular in those with complete left bundle branch block. Unfortunately, a significant number of patients (30%–40%) have no response to CRT. This lack of response could be explained by inappropriate pacing site selection, suboptimal device programming, or absence of dysynchronous basal LV contraction. Another limitation could be that pacing from a single LV point is incapable of generating a coordinated mechanical activation. Quadrupolar electrodes would allow LV pacing from 2 points far
